

Graphite

1 Properties

① Covalent bonds

- Each C atom shares 3 bonding e^- w/ neighbouring atoms

② The unbonded electron

- The unbonded outermost shell e^- is delocalised.
It can move across & between layers. → electrical conductivity
- 'p' shaped orbital allows it to move between layers
- It can sometimes form covalent bonds w/ atoms → partial double bond

③ Graphene

- Graphene = 1 single layer of graphite

④ VDW forces

- Weak VDW forces exist w/ 2 layers → allow graphene layers to slide over each other.
- Graphite is used as pencil / lubricant.

2 Example question

Compare distances a, b, c.

force →

F_a & F_c, F_b :

- a, c: covalent bond
- b: VDW force
- break VDW require ∇ energy than bond
- $F_{a,c} > F_b$

F_a, F_c :

- a: C-C partial double bond
- c: C-C single bond
- bond strength of partial double > single
- $F_a > F_c$

$$\text{Distance} \propto \frac{1}{\text{force}}$$

$$\therefore a < c < b$$
